1. Incident Neutron Energy: 0.0253eV: Effective Fission

Distance Reff derived from experimental charge distribution

Analysis Results

Calculation results demonstrating that the effective fission distance Reff derived from optimization calculations accurately reproduces experimental values (confirming agreement between JENDL-5 experimental and theoretical values, and validating calculations using Mathematica ver11.2 FindMinimum)

2. Incident Neutron Energy: 500keV: Effective Fission

Distance Reff derived from experimental charge distribution

Analysis Results

Calculation results demonstrating that the effective fission distance Reff derived from optimization calculations accurately reproduces experimental values (confirming agreement between JENDL-5 experimental and theoretical values, and validating calculations using Mathematica ver11.2 FindMinimum)

3. Incident Neutron Energy: 14MeV: Effective Fission

Distance Reff derived from experimental charge distribution

Analysis Results

Calculation results demonstrating that the effective fission distance Reff derived from optimization calculations accurately reproduces experimental values (confirming agreement between JENDL-5 experimental and theoretical values, and validating calculations using Mathematica ver11.2 FindMinimum)

Analysis Results:

1. The effective fission distance R_{eff} shows quadratic dependence on fragment charge
2. This dependence reflects fundamental laws of charge distribution in fission process
3. Similar dependence is maintained across different incident energies

Incident Neutron Energy: 0.0253 eV case

$$R_{\text{eff}} = -0.410266 + 0.000734641 (94.004 - x) x$$

Incident Neutron Energy: 500 keV case

$$R_{\text{eff}} = -0.470383 + 0.000759686 (93.999 - x) x$$

Incident Neutron Energy: 14 MeV case

$$R_{\text{eff}} = -0.467317 + 0.00077411 (94.0457 - x) x$$

Analysis Results:

1. The effective fission distance R_{eff} shows quadratic dependence on fragment charge number
2. This dependence reflects fundamental laws of charge distribution in the fission process
3. Similar dependence is maintained across different incident energies

Analysis of Fission Yields: Comparison

between Experimental Data and Theoretical Calculations ($E_x=0$)

Theoretical Analysis Results using Effective

Fission Distance R_{eff} proportional to fragment charge product,

with zero Fermi Energy ($E_x=0$)

- Quantitative reproduction of experimentally observed asymmetric fission yield distributions

1. Analysis for Incident Neutron Energy: 0.0253eV

2. Analysis for Incident Neutron Energy: 500keV

3. Analysis for Incident Neutron Energy: 14MeV

Analysis of Effective Fission Distance and Fission Probability

Analysis Contents:

1. Calculation of Effective Fission Distance (R_{eff}) for each incident neutron energy
2. Evaluation of fission probability using η function
3. Derivation of normalization factor κ ($= E_x/R_{eff}$)

The vertical axis κ represents the ratio of Fermi Energy (E_x) to effective fission distance (R_{eff}).

$\kappa \approx 1$ suggests the fission Fermi Energy is proportional to effective distance.

Theoretical Analysis and Experimental Comparison of Fission Yield Distributions

Calculation Process:

1. Evaluate logarithmic differences
between JENDL-5 experimental data and theoretical calculations
2. Optimize Fermi Energy (E_x) using least squares method
3. Generate theoretical curves using optimized E_x
4. Compare and verify experimental vs theoretical values

Optimization Goals:

- Theoretical reproduction of experimentally observed asymmetric fission yields
- Understanding fission mechanisms at each incident neutron energy
- Systematic determination of Fermi Energy (E_x)

Evaluation Methods:

- Minimize sum of squared logarithmic differences between theory and experiment
 - Parameter optimization using FindMinimum function
 - Validation of theoretical curves with optimized parameters
-
